Lesson:

Embedding JS expressions in JSX

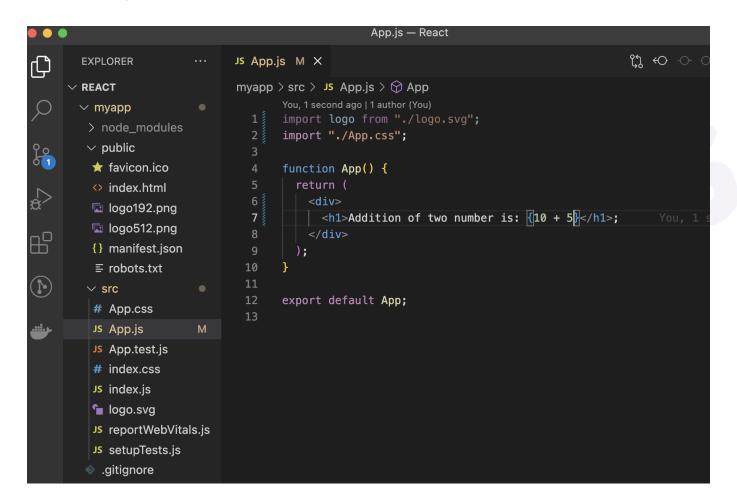

Topics Covered:

1. Embedding JS expressions in JSX

Embedding JS expressions in JSX

Since JSX is a JavaScript extension, it will accept any valid JavaScript expressions enclosed in curly brackets '{}'. This enables you to add dynamic elements to your JSX.This can be a string, a number, a boolean, an object, or even an array.

Here is a example:

Output will be:

Addition of two number is: 15

Inside the curly braces, we can also use variables in Jsx. For example:

```
Ϋ́, ←Ο -○- ○> Φ
 EXPLORER
                        JS App.js M X
✓ REACT
                        myapp > src > JS App.js > ...
 > node_modules
                               import "./App.css";
                           2 🖁
 ∨ public
  ★ favicon.ico
                               function App() {
                               const course = "WebDev";
  index.html

    □ logo192.png

  <h1>Welcome to, {course}</h1>;
  {} manifest.json

    robots.txt

 ∨ src
  # App.css
                               export default App;
  JS App.js
  JS App.test.js
  # index.css
  Js index.js
  logo.svg
  JS reportWebVitals.js
  JS setupTests.js
 .gitignore
 {} package-lock.json
```

Output will be Welcome to, Webdev

Welcome to, WebDev

Notes:

We can only use expressions that return a single value inside the curly braces in JSX. For example, the following code would be invalid:

```
App.is — React
                      JS App.js 2, M X
                                                                                ξή ↔
                      myapp > src > JS App.js > ♦ App
                             You, now | 1 author (You) import logo from "./logo.svg";

∨ myapp

 > node modules

∨ public

 * favicon.ico
                             function App() {
 o index.html
 🖾 logo192.png
                             logo512.png
 {} manifest.json

    robots.txt

 ∨ src
                             export default App;
 # App.css
 JS App.test.js
 # index.css
 Js index.js
```

instead, We would need to wrap the expressions in parentheses to make it a single expression: Also we can use a div tag to wrap both the elements.

Instead of using **React.fragment**, we use an empty tag($\langle \cdot \rangle \langle \cdot \rangle$).

```
ţ'n ← → → (•
       EXPLORER
                              JS App.js M •
                               myapp > src > JS App.js > 分 App

✓ REACT

∨ myapp

                                      import logo from "./logo.svg";
        > node_modules
                                    import "./App.css";

∨ public

         * favicon.ico
                                    function App() {
         index.html

    □ logo192.png

                                          < h1>Addition of two number is: {(10 + 5) + (23 + 40)}</h1>;
         🗔 logo512.png
         {} manifest.json
         (\mathbf{1})
                                      export default App;
         # App.css
         JS App.js
```

Inline Styling with JSX

Without creating an object we can directly write the element inside curly braces.
